Extraction of Lead Ions and Partitioning Behavior in Aqueous Biphasic Systems Based on Polyethylene Glycol and Different Salts

Kridsada Aunnankat, Ura Pancharoen, Worapon Kiatkittipong, Mali Hunsom, Farid Aiouache, Vesna Najdanovic-Visak,* and Prakorn Ramakul*

ABSTRACT: Lead ions are environmental pollutants often present in very low concentrations, which makes them difficult to detect and, thus, present problems for environmental monitoring. In this study, we examined the performance of aqueous biphasic systems based on polyethylene glycol (PEG, molecular mass of 4000 g mol⁻¹) with ammonium sulfate $(NH_4)_2SO_4$, magnesium sulfate $(MgSO_4)$, sodium sulfate (Na_2SO_4) , and trisodium citrate $(Na_3C_6H_5O_7)$ for the separation of lead(II) ions from aqueous solutions. We investigated the effects of salt types and the ratio of PEG4000 to salt on the extraction efficiency of lead(II) removal at constant temperatures of 303 K and 0.1 MPa. Additionally, we determined the cloud points (solubility equilibrium curve) and tie-lines for four ternary systems comprising PEG4000, water, and salt (either $(NH_4)_2SO_4$, MgSO₄, Na₂SO₄, or Na₃C₆H₅O₇) under the same conditions. A maximum lead(II) extraction efficiency of 74.4% was achieved using the PEG4000/ $(NH_4)_2SO_4$ system with a mass fraction ratio of PEG4000 to $(NH_4)_2SO_4$ of 0.2:0.12. This outcome highlights the significant potential of utilizing aqueous biphasic systems based on PEG4000 to separate lead(II) from aqueous solutions efficiently.

1. INTRODUCTION

Lead (Pb) is a heavy metal resistant to corrosion and radiation and, thus, widely used in various industries, including semiconductors, nuclear, mining, steel, and metallurgy.^{1–3} Market demand for lead has increased in the past decade⁴ due to the recent development in electronic devices, batteries, and cables.⁵ Although the mineral industry has developed a highly efficient ion-exchange resin process for lead recovery, lead is still released into the environment with wastewater and distributed in the atmosphere, soil, and water.^{2,3}

Due to its toxicity, the released lead can severely affect the environment and human health.^{6,7} Plants and animals can ingest it since it accumulates in soil, water, and air. Contaminated soil and water are unsuitable for growing crops or other vegetation, harming aquatic life and reducing water quality.⁸ Lead exposure can cause neurological problems in adults, developmental problems in children, and cardiovas-cular problems, including high blood pressure and heart disease.⁹ Thus, improving its removal and disposal is paramount to preventing adverse effects.

Several processes were used to remove and separate heavy metal ions from natural waters, industrial wastewater, and contaminated soil.¹ The liquid–liquid extraction,¹⁰ cation adsorption,⁶ electrochemical treatment,¹¹ coagulation–flocculation,¹² and biosorption¹³ were reported to remove lead from aqueous solutions. In this context of separation, the aqueous two-phase system (ATPS) is more efficient than the typical liquid–liquid extraction in hydrometallurgical processes and has an intriguing possibility for use in the metal recovery process.^{14,15} The characteristics of ATPS take advantage of being nonflammable, nontoxic, and less harmful than organic solvents^{16–18} as well as exhibiting lower interfacial tension.^{19–21} Therefore, the ATPS technique is used in hydrometallurgical processes to selectively recover metals.^{16,19} The

ATPS is created by combining two aqueous solutions (such as polymer/salt or polymer/polymer systems). After complete phase separation, two liquid phases are formed: a polymer-rich top phase (TP) and a salt-rich bottom phase (BP).²²

ATPS systems have been reported to extract lead from aqueous solutions, as summarized in Table 1. In 2012, Debashree Das et al.²³ used an ATPS consisting of a nonionic surfactant Triton X-100 in combination with trisodium citrate $(Na_3C_6H_5O_7)$ and magnesium sulfate $(MgSO_4)$ for the extraction of lead (Pb(II)) from lead dithizone complex. They found that Pb from lead dithizone complex was not extracted in the Triton phase even though lead (Pb(II)) from a metal mixture (Hg, Bi, and Pb) was completely extracted at pH 8.9. In addition, Kaustab Ghosh et al.²⁴ studied the separation of no-carrier-added (NCA) ²⁰³Pb (lead radionuclide) from proton irradiated ^{nat}Tl₂CO₃ target and found that about 60% of NCA ²⁰³Pb was extracted by using an ionic liquid, 1-butyl-3methylimidazolium chloride ([bmim]Cl), and K_2HPO_4 salt ATPS system. To the best of our knowledge, there is only one report on using aqueous biphasic systems based on polyethylene glycol, namely, PEG1500/(NH₄)₂SO₄ and PEG1500/ NaCl, to extract lead ions.²⁵ The authors reported that the maximum extraction yield was 51.8%.

In this study, we report the ATPS based on PEG4000 with either magnesium sulfate, sodium sulfate, ammonium sulfate, or trisodium citrate to extract lead ions (Pb(II)) from water at 303 K. Reported data include cloud points, solubility curves, critical points, tie-lines, partition coefficients, and extraction efficiencies.

2. EXPERIMENTAL SECTION

2.1. Materials and Chemicals. All chemicals used in this work are summarized in Table 2. Polyethylene glycol (PEG) with a molar mass of 4000 g mol⁻¹ was purchased from Merck, Sigma-Aldrich. Ammonium sulfate $((NH_4)_2SO_4)$ with purity \geq 99.5 mass% was acquired from QReC. Magnesium sulfate

 $(MgSO_4)$ with purity \geq 99 mass% was obtained from KemAus, while sodium sulfate (Na_2SO_4) with purity \geq 99 mass% and trisodium citrate dihydrate $(Na_3C_6H_5O_7)$ with purity \geq 99 mass% was obtained from Loba Chemie PVT Ltd. Lead (Pb(II)) standard solution (1000 mg L⁻¹) (Pb(NO_3)₂ in HNO₃ 0.5 mol L⁻¹) was purchased from PanReac AppliChem. Deionized water by MSECO DI-15A was used for solution preparations. All mixtures were gravimetrically prepared using an analytical balance (Sartorius TE214S with an accuracy of 0.0001 g).

2.2. Cloud Points (Solubility Curves). Cloud points of the ternary mixtures containing PEG4000, water, and salt (either Na₂SO₄, (NH₄)₂SO₄, Na₃C₆H₅O₇, or MgSO₄) were determined by the titration method at a constant temperature of 303 K and at a pressure of 0.1 MPa as described in our previous work.²⁶ Binary mixtures containing water and PEG4000 (40mass% PEG4000) were placed in septum-sealed glass vials with a magnetic stirrer bar. The vials were then immersed in a temperature-controlled bath using a complete set of heating and magnetic stirring equipment (C-MAG HS 7) with a temperature setting accuracy of 303 K (\pm 1 K). The binary mixtures were slowly titrated with aqueous salt solutions of 25 mass% Na₂SO₄, 25 mass% (NH₄)₂SO₄, 25 mass% Na₃C₆H₅O₇, and 20 mass% MgSO₄ until the first turbidity was observed, which was taken as a cloud point. The final mixtures were weighed to calculate the composition corresponding to the cloud point. Three replicates of each assay were performed to validate the experimental method, and the average reproducibility of the composition of cloud points (in mass fraction) was ± 0.003 .

The cloud point data were correlated by Merchuck's equation²⁷⁻²⁹

$$x_{\text{PEG}} = A \cdot \exp[B \cdot x_{\text{salt}}^{0.5} - C \cdot x_{\text{salt}}^{3}]$$
(1)

where x_{PEG} and x_{salt} are the mass fractions of PEG4000 and salt, respectively. The parameters *A*, *B*, and *C* were estimated

ASE (%) =
$$\frac{1}{N} \sum_{i} \frac{|x_{\text{pEG},i}^{\text{exp}} - x_{\text{pEG},i}^{\text{calc}}|}{x_{\text{pEG},i}^{\text{exp}}} \times 100$$
 (2)

where $x_{\text{PEG},i}^{\exp}$ and $x_{\text{PEG},i}^{\text{calc}}$ are the experimental and calculated mass fractions of PEG4000, respectively, and N is the number of cloud point data.

2.3. Tie-Lines (TLs) and Critical Points. The methodology used for the tie-line determination has been described previously in great detail.^{20,29} Here, only a short description is provided. Selected compositions of ternary mixtures containing PEG4000, water, and salt (either Na₂SO₄, (NH₄)₂SO₄, $Na_3C_6H_5O_7$, or MgSO₄) were prepared gravimetrically in 15 mL glass vials. First, the glass vials were agitated for at least 2 h at a controlled temperature of 303 ± 1 K in a temperaturecontrolled bath using a complete set of heating equipment (C-MAG HS 7). Subsequently, the agitation was stopped, and mixtures were left still for at least 12 h. This was maintained at a consistent temperature using a temperature-controlled bath set to 303 ± 1 K. After this period, a complete phase separation was observed, with the top phase being PEG4000rich and the bottom phase being salt-rich. Both phases were carefully separated and individually weighed using a Sartorius TE214S analytical balance (an accuracy of ± 0.0001 g). The same experiment was repeated several times using different equilibrium times, and it was estimated that 2 h was sufficient to reach equilibrium. For convenience, the samples were left for at least 12 h.

The parameters A, B, and C obtained by the experimental regression of the composition cloud points from eq 1 and the lever-arm rule were used to calculate the composition of PEG4000 and salt in the top and bottom phases of each individual TL. The following set of equations are obtained

$$x_{\text{PEG}}^{\text{TP}} = A \cdot \exp[B \cdot (x_{\text{salt}}^{\text{TP}})^{0.5} - C \cdot (x_{\text{salt}}^{\text{TP}})^3]$$
(3)

$$x_{\text{PEG}}^{\text{BP}} = A \cdot \exp[B \cdot (x_{\text{salt}}^{\text{BP}})^{0.5} - C \cdot (x_{\text{salt}}^{\text{BP}})^3]$$
(4)

$$x_{\text{PEG}}^{\text{Total}} \cdot m_{\text{Total}} = x_{\text{PEG}}^{\text{BP}} \cdot m_{\text{BP}} + x_{\text{PEG}}^{\text{TP}} \cdot m_{\text{TP}}$$
(5)

$$x_{\text{salt}}^{\text{Total}} \cdot m_{\text{Total}} = x_{\text{salt}}^{\text{BP}} \cdot m_{\text{BP}} + x_{\text{salt}}^{\text{TP}} \cdot m_{\text{TP}}$$
(6)

where m_{Tota} , m_{TP} , and m_{BP} are the overall mass of the mixture, mass of the top phase, and mass of the bottom phase, respectively. The unknown variables $x_{\text{PEG}}^{\text{TP}}$ and $x_{\text{salt}}^{\text{TP}}$ are the mass fraction of the PEG4000 and salt in the top phase, respectively, while $x_{\text{PEG}}^{\text{BP}}$ and $x_{\text{salt}}^{\text{BP}}$ are the mass fraction of the PEG4000 and salt in the bottom phase, respectively. Four unknown variables ($x_{\text{PEG}}^{\text{TP}}$, $x_{\text{PEG}}^{\text{TP}}$, $x_{\text{PEG}}^{\text{TP}}$, and $x_{\text{PEG}}^{\text{TP}}$) in a nonlinear set of eqs 3–6 were solved by the Solver tool in Microsoft Excel (Version 2304).

The slope of the tie-line (STL) was calculated by the ratio between the mass fraction difference of PEG4000 and salt (either Na_2SO_4 , $(NH_4)_2SO_4$, $Na_3C_6H_5O_7$, or $MgSO_4$) in the top and bottom phases according to

$$STL = \frac{x_{PEG}^{TP} - x_{PEG}^{BP}}{x_{salt}^{TP} - x_{salt}^{BP}}$$
(7)

Tie-line length (TLL) was calculated by the square root of the sum of the squares of the differences of PEG4000 and salt mass fractions in the coexisting phases according to eq 8:

$$TLL = \sqrt{(x_{PEG}^{TP} - x_{PEG}^{BP})^2 + (x_{salt}^{TP} - x_{salt}^{BP})^2}$$
(8)

The critical point (CP) for each ternary system was estimated using the so-called law of rectilinear diameter.³⁰ First, the midpoints of each tie-line were plotted as a function of x_{salt} in the phase diagram, which defined the associated straight line using linear regression

$$x_{\rm PEG}^{\rm mid-point} = f x_{\rm salt}^{\rm mid-point} + g \tag{9}$$

where $\frac{\text{midpoint}}{\text{PEG}}$ and $x_{\text{salt}}^{\text{midpoint}}$ are the mass fractions of PEG4000 and salt at the midpoint, respectively, while *f* and *g* are the fitting parameters. Finally, the critical point was determined as the interception of the line defined by eq 9 and the experimental binodal curve.

2.4. Partition Coefficient and Extraction Efficiency. The investigation of the partition coefficient of lead (Pb(II))ion experiments was carried out in glass vials (15 mL) with a magnetic stirrer using the temperature-controlled bath at 303 ± 1 K. The composition of PEG4000, distilled water, and salt (either Na_2SO_4 , $(NH_4)_2SO_4$, $Na_3C_6H_5O_7$, or $MgSO_4$) was selected in such a way to form the aqueous biphasic system. The ternary mixtures were agitated by a magnetic stirrer at the same temperature. Subsequently, 100 μ L of lead (Pb(II)) standard solution (1000 mg L^{-1}) was added to the ternary mixtures. Therefore, the total mass of the Pb(II) $(m_{\rm M}^{\rm Total})$ in all experiments was 0.1 mg. The mixtures were agitated for at least 2 h and then left still for at least 12 h at the constant temperature to reach equilibrium and complete phase separation. The bottom phase from the mixture was transferred to a 15 mL sample vial using a syringe. The samples were prepared for further analysis to determine the concentration of Pb(II) ions in the bottom phase (C_M^{BP}) using flame atomic absorption spectrometry (Flame-AAS, Analyst 200 + flas 400; PerkinElmer).

The mass of Pb(II) in the bottom phase (m_M^{BP}) was calculated using the previously determined C_M^{BP} value and the volume of the bottom phase (V_{BP}) determined by multiplying the density of the bottom phase by the measured mass of that phase, according to

$$m_{\rm M}^{\rm BP} = C_{\rm M}^{\rm BP} \cdot V_{\rm BP} \tag{10}$$

The mass of Pb(II) in the top phase (m_M^{TP}) and the Pb(II) concentration in the top phase (C_M^{TP}) were calculated according to eqs 11 and 12

$$m_{\rm M}^{\rm TP} = m_{\rm M}^{\rm Total} - m_{\rm M}^{\rm BP} \tag{11}$$

$$C_{\rm M}^{\rm TP} = \frac{m_{\rm M}^{\rm TP}}{V_{\rm TP}} \tag{12}$$

where $V_{\rm TP}$ is the volume of the top phase determined by multiplying the density of the bottom phase by the measured mass of that phase.

The partition coefficient was calculated using the following equation

$$K = \frac{C_M^{\rm TP}}{C_M^{\rm BP}} \tag{13}$$

where C_{M}^{TP} and C_{M}^{BP} are the concentrations of Pb(II) (mg L⁻¹) in the top and bottom phases, respectively.

The extraction efficiency (EE) was calculated using the following equation

 x_{salt} (mass fraction)

Figure 1. Experimental solubility curves for the ternary mixtures containing polyethylene glycol (PEG4000), water, and salt (Na₂SO₄ (\blacksquare), (NH₄)₂SO₄ (\blacktriangle), Na₃C₆H₅O₇ (\bullet), and MgSO₄ (\blacklozenge)), in mass fractions. Solid curves present fittings obtained by eq 1 using the obtained parameters given in Table 3. r^2 and ASE are the coefficient of determination and average standard error (eq 2), respectively.								

$$EE (\%) = \frac{m_{\rm M}^{\rm TP}}{m_{\rm M}^{\rm Total}} \times 100$$
(14)

where m_M^{TP} is the mass of Pb(II) in the top phase and m_M^{Total} is the total mass (feed) of Pb(II) in the system.^{22,28}

All presented results are the average of three replicate analyses. The maximum observed standard error for obtained partition coefficients for different replicas of the same assays is <3%.

3. RESULTS AND DISCUSSION

3.1. Cloud Points. Table S1 in the Supporting Information presents experimental cloud points for the ternary mixtures containing PEG4000, water, and salt (either Na₂SO₄, $(NH_4)_2SO_4$, $Na_3C_6H_5O_7$, or $MgSO_4$) at 303 K and at a pressure of 0.1 MPa. These data were used to construct binodal lines, as shown in Figure 1. The area above and below the binodal curves denotes the two-phase and single-phase regions, respectively. Components with a high phase segregation capacity are indicated by a binodal curve positioned closer to the origin, signifying that lower concentrations of the constituents are needed to form a biphasic mixture. Both the type and concentration of salt significantly impacted the phase behavior. In general, the ability of salt to induce phase separation followed the order $Na_2SO_4 > (NH_4)_2SO_4 > Na_3C_6H_5O_7 > MgSO_4$. The experimental results for cloud points are consistent with the findings of Reinert Ramos Gandolfi et al.,¹⁸ who reported the

cloud points of PEG4000 and salts (Na_2SO_4 and $Na_3C_6H_5O_7$) (white marker squares and circles in Figure 1).

The cloud point data were correlated using eq 1, as presented in Figure 1. The obtained parameters *A*, *B*, and *C* for each biphasic system are shown in Table 3, along with the coefficient of determination (r^2) and the average standard error (ASE) calculated according to eq 2. Correlations are reasonably good, with average standard deviations of 20.4%, 10.4%, 9.2%, and 8.7% for solutions with Na₂SO₄, (NH₄)₂SO₄, Na₃C₆H₅O₇, and MgSO₄, respectively. The obtained parameters *A*, *B*, and *C* were used to quantify the amount of each component in the top and bottom phases of the tie-lines by the lever rule.

3.2. Tie-Lines and Critical Points. Figure 2 shows the cloud point curves with corresponding tie-lines for ternary solutions containing polyethylene glycol (PEG40000), water, and salt $(Na_2SO_4, (NH_4)_2SO_4, Na_3C_6H_5O_7, and MgSO_4)$ at 303 K and at 0.1 MPa. All tie-line data are included in Supporting Information Table S2, along with the slope of the tie-line (STL) and tie-line length (TLL) calculated using eq 7 and eq 8, respectively. The increase in the overall salt or PEG4000 concentration enlarged the tie-line length for the four studied systems, indicating a larger difference between the compositions of the top and bottom phases (a higher degree of separation).

The critical points (x_{PEG}^{CP} and x_{Salt}^{CP}), resulting from the intersection of the linear equation (eq 9) with the binodal curve presented in Figure S1, for each ternary system are given

Figure 2. Cloud point curves (solid line) and corresponding tie-lines (dashed lines) for ternary solutions containing polyethylene glycol (PEG40000), water, and salt at 303 K and at 0.1 MPa: Na₂SO₄ (a); (NH₄)₂SO₄ (b); Na₃C₆H₅O₇ (c); MgSO₄ (d). A polymer and salt composition in mass fraction (x_{PEG4000} and x_{salt}) where the partitioning behavior of Pb(II) was evaluated (blue \bullet); critical point (red \bullet). Solid curves present fittings obtained by eq 1 using parameters given in Table S1 in the Supporting Information.

Table 4. Critical Points of Four Ternary Systems Containing Polyethylene Glycol 4000 g mol⁻¹ (PEG4000), Water, and Salt (Either Na₂SO₄, (NH₄)₂SO₄, Na₃C₆H₅O₇, or MgSO₄) at 303 K and 0.1 MPa^{*a*}

	The Linear Equation Tie-Line Relation			Critical Point	
System	f	g	r^2	$x_{\rm PEG}^{ m CP}$	x_{Salt}^{CP}
PEG4000 + water + Na_2SO_4	1.877	0.057	0.9611	0.155	0.052
PEG4000 + water + $(NH_4)_2SO_4$	2.843	-0.182	0.9543	0.095	0.098
PEG4000 + water + $Na_3C_6H_5O_7$	1.663	-0.023	0.9719	0.137	0.096
PEG4000 + water + MgSO ₄	1.317	-0.054	0.9692	0.110	0.125

"Parameters *f* and *g* of eq 9 were fitted to the linear equation formed by the tie-line relation points, and r^2 is the coefficient of determination. x_{PEG}^{CP} and x_{Salt}^{CP} are the mass fractions of the PEG4000 and salt at the critical point.

in Table 4. The table also includes the fitting parameters (f and g) of the linear equation obtained from the tie-line relation point. The critical points of all the investigated systems are also illustrated in both Figures 1 and 2. In the case of SO₄²⁻-based systems, salt composition at the critical point varies among all the studied systems. However, the composition of PEG4000 is similar for the (NH₄)²⁺ and Mg²⁺ systems but is significantly different from the Na⁺ system. When comparing the system of (NH₄)₂SO₄ with Na₃C₆H₅O₇, which differ in both the anion and cation, it was found that the salt concentration at the critical point was very similar, and the concentration of PEG4000 was different.

Table S1 in the Supporting Information shows that the bottom phase of the systems had a greater water concentration

than the upper phase. This is because salts and water have a higher degree of similarity in terms of their polarity compared to the weakly polar PEG group, which leads to a stronger electrostatic interaction between water molecules and salts. The cations Na⁺, NH₄⁺, and Mg²⁺ and the anions C₆H₅O₇³⁻ and SO₄²⁻ of salts interact significantly with water, affecting the hydrogen-bonding structure and thus their reactivity via the solubility property in water.³¹

3.3. Partition Coefficient (K_{Pb}) and Extraction Efficiency (%EE) of Lead (Pb(II)) lons. The partition coefficient (K_{Pb}) and extraction efficiency (%EE) of lead (Pb(II)) ion in the mixtures containing PEG4000, water, and salt (Na₂SO₄, (NH₄)₂SO₄, Na₃C₆H₅O₇, and MgSO₄) are provided in Table 5 as a function of the overall concentration, along with

^{*a*}The initial concentration of lead ion (Pb(II)) in the feed solution was 17.540 mg L⁻¹. x_{PEG} , x_{salt} , and x_{water} are the mass fractions of PEG4000, salt, and water, respectively. $C_{Pb}^{Top Phase}$ and $C_{Pb}^{Bottom Phase}$ are the concentrations of Pb(II) in the top and bottom phases, respectively. The standard uncertainties u are $u(x) = \pm 0.003$, $u(C_{Pb}) = \pm 0.003$ mg L⁻¹, $u(T) = \pm 1$ K, and $u(p) = \pm 1$ kPa.

concentrations of lead (Pb(II)) ion in the top and bottom phase. As can be observed from Figure 3, K_{Pb} and EE were affected by the type of salt and composition of polymer per salt. The highest extraction efficiency of 74.7% was observed for the ATPS containing (NH₄)₂SO₄. Compared with the previous studies summarized in Table 1, this result is significantly higher than that for other ATPS based on polyethylene glycol^{24,25} but lower than some ATPS based on octyl phenol ethoxylate.²³ The second-highest extraction was achieved for the MgSO₄ system.

The partition coefficient in the Na₂SO₄ and Na₃C₆H₅O₇ systems at all studied concentrations is less than unity, meaning that Pb(II) ion is more concentrated in the salt-rich phase. On the contrary, for the $(NH_4)_2SO_4$ and MgSO₄ systems, the results indicate that the Pb(II) ion has a greater affinity for the more hydrophobic phase ($K_{Pb} > 1$), which is the PEG-rich phase.

The tie-line length (TLL) is a parameter that indicates the difference in compositions between the polymer-rich and saltrich phases in a liquid-liquid extraction system. It quantifies the extent of phase separation and reflects the influence of the two phases' compositions on the partitioning behavior of specific components, such as Pb(II) in this case. A longer tieline length implies a larger two-phase region, providing more opportunities for the metal ions to partition between the phases. The blue solid points in Figure 2 represent a polymer and salt composition where the partitioning behavior of Pb(II) was evaluated, along with the TLL provided in Table 5. In the Na₃C₆H₅O₇ and MgSO₄ systems, an increased tie-line length led to a higher Pb(II) partitioning coefficient, indicating a stronger affinity of the metal ions for the polymer-rich phase. This could be attributed to specific interactions or complexations between Pb(II) and the polymer or salt components in these systems. On the other hand, in the Na_2SO_4 and $(NH_4)_2SO_4$ systems, an increase in tie-line length resulted in a decreased partitioning coefficient of Pb(II), indicating a reduced affinity for the polymer-rich phase. The reasons for this could include changes in the solvation or complexation behavior of Pb(II) with the salt and polymer components, 32-40leading to a different distribution pattern. The variations in the polymer and salt concentrations in each phase can have a significant impact on the partitioning behavior of Pb(II) and are important factors to consider when designing and

optimizing the ATPS system for the extraction and separation of Pb(II).

The partitioning of Pb(II) can be explained by the intermolecular forces in the mixture between metal ions with anions, complex metal with anions, and complex metal with polymer. The Pb(II) cation exists in different forms in the initial solution and in two phases in equilibrium: polymer- and salt-rich phases. The interaction mechanism between Pb(II) ions and the components in the ATPS can be described according to the research literature.^{32–40} In the salt-rich phase, the Pb²⁺ cation forms a complex with the salt anion (SO₄^{2–} and C₆H₅O₇^{3–}) and water molecules, according to

$$Pb^{2+} + 2SO_4^{2-} \rightleftharpoons [Pb(SO_4)_2]^{2-}$$
 (15)

$$Pb^{2+} + C_6H_5O_7^{3-} \rightleftharpoons [Pb(C_6H_5O_7)]^-$$
 (16)

$$Pb^{2+} + 6H_2O \rightleftharpoons [Pb(H_2O)_6]^{2+}$$
 (17)

These complexes can establish hydrogen bonds with polyethylene glycol molecules^{36,39} primarily by interaction through ionic forces with PEG ether oxygen atoms,³³ enhancing their transfer into the PEG-rich phase:

$$[Pb(SO_4)_2]^{2-} \rightleftharpoons [[Pb(SO_4)_2]^{2-}]_{(PEG)}$$
(18)

$$[Pb(C_6H_5O_7)]^- \rightleftharpoons [[Pb(C_6H_5O_7)]^-]_{(PEG)}$$
(19)

$$[Pb(H_2O)_6]^{2+} \rightleftharpoons [[Pb(H_2O)_6]^{2+}]_{(PEG)}$$
(20)

On the other hand, some Pb^{2+} cations will be retained in the bottom (salt-rich) phase due to interactions between the Pb(II) ions and the components of the ATPS, as described by eqs 15–17.

4. CONCLUSION

This work focused on studying a polymer-based aqueous twophase system for extracting Pb(II) ions. Aqueous two-phase system (ATPS) equilibrium data for the ternary mixtures (PEG4000 + Na₂SO₄ + water), (PEG4000 + (NH₄)₂SO₄ + water), (PEG4000 + Na₃C₆H₅O₇ + water), and (PEG4000 + MgSO₄ + water) were obtained at 303 K and at atmospheric pressure. The ability of salt to induce phase separation followed the order Na₂SO₄ > (NH₄)₂SO₄ > Na₃C₆H₅O₇ > MgSO₄. The Pb(II) ion extraction was carried out at room

Figure 3. Partition coefficients of lead ion (Pb(II)) (K_{Pb}) (a) and extraction efficiency (%EE) (b), in biphasic systems composed of polyethylene glycol (PEG4000), water, and salt (Na₂SO₄, (NH₄)SO₄, Na₃C₆H₅O₇, and MgSO₄) at 303 K and at 0.1 MPa, for different initial compositions in mass fraction ($x_{PEG4000}/x_{salt}$). The initial concentration of lead ion Pb(II) in the feed solution was 17.54 mg L⁻¹ in all partitioning experiments.

temperature, and the behavior of Pb(II) ions in ATPS was demonstrated through the assessment of the partition coefficient and extraction efficiency. The maximum extraction efficiency of Pb(II) was 74.7% achieved with a mass fraction of PEG4000 per salt ratio of 0.2:0.12 in the PEG4000/ $(NH_4)_2SO_4$ system. The performance order of Pb(II) ion extraction efficiency was 74.7%, 67.7%, 37.8%, and 24.2% for $(NH_4)_2SO_4$, MgSO₄, Na₂SO₄, and Na₃C₆H₅O₇ systems, respectively. This suggests that the SO₄²⁻ anion system could be a suitable option for extracting Pb(II) from aqueous solutions, particularly by utilizing $(NH_4)_2SO_4$ and MgSO₄ salts

as additives in the PEG4000-based ATPS system for Pb(II) separation.
